## Metropolis-Hastings for Beta distribution

We write a Metropolis-Hastings algoritm to generate  $X\sim beta(6,4)$ . We select a r.v. from unif(0,1) as a starting value and a  $Beta(c\phi old, c(1-\phi old))$  jumping distribution where c is a parameter in our function. Later on we can test MH algoritm with different c's. 10 percent of iterations will be treated as burn-in

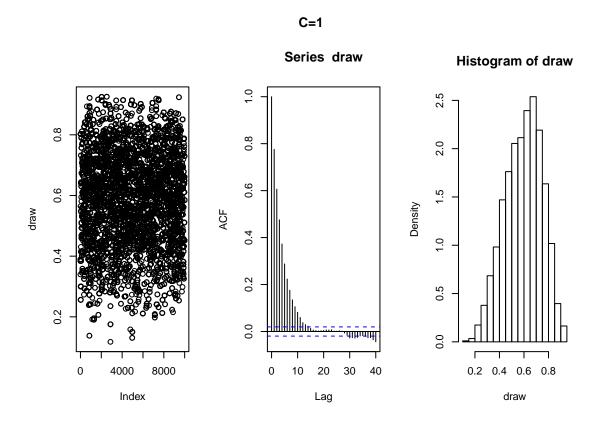

```
MHalg<-function(iter,c){</pre>
  phi<- c()
  phi[1] <-runif(1,0,1) #generate a starting value from unif(0,1)</pre>
  new_phi<- function(phi) {</pre>
    proposal_phi <- rbeta(1, shape1= c*phi , shape2= c*(1-phi) ) #giving jumping dist.</pre>
    # ratio of accepting proposal_phi
    r <- (dbeta(proposal phi, shape1 = 6, shape2 = 4)/
          dbeta(proposal_phi, shape1= c*phi , shape2=c*(1-phi)))/
          (dbeta(phi, shape1 = 6, shape2 = 4)/
          dbeta(phi, shape1= c*proposal_phi, shape2=c*(1-proposal_phi)))
    if (runif(1) <= r)</pre>
      return(proposal_phi)
      return(phi)
  }
  for (i in 1:iter)
    phi[i+1] = new_phi(phi[i])
  phi=phi[-(iter/10)] #truncate burn-in
}
```

```
a1=rbeta(10000,6,4)
hist(a1,freq=FALSE,main="beta(6,4) histogram")
```

We first start a simulation with c=1, and 10000 draws. Perform KS test to determine whether our generated random variables are numerically approximately follow Beta(6,4)

```
draw=MHalg(10000,1)
par(mfrow=c(1,3),oma=c(2,2,2,2))
plot(draw); acf(draw); hist(draw,freq=FALSE)
title("C=1", outer=TRUE)
```

```
## Warning in ks.test(draw, a1): p-value will be approximate in the presence
## of ties

##
## Two-sample Kolmogorov-Smirnov test
##
## data: draw and a1
## D = 0.0284, p-value = 0.0006283
## alternative hypothesis: two-sided
```

ks.test(draw,a1)

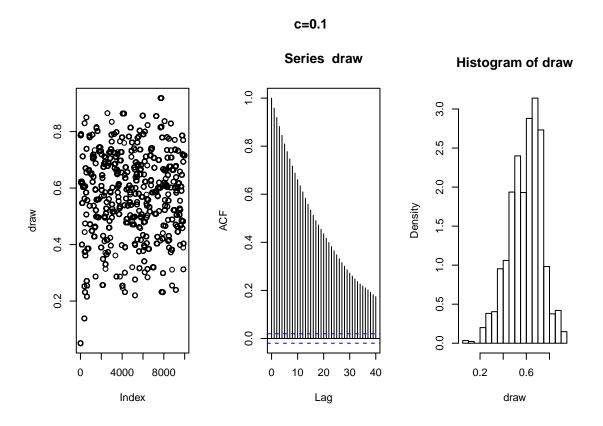

Now we simulate with c=0.1, 2.5, 10.

```
draw=MHalg(10000,0.1)
par(mfrow=c(1,3),oma=c(2,2,2,2))
plot(draw); acf(draw); hist(draw,freq=FALSE)
ks.test(draw,a1)

## Warning in ks.test(draw, a1): p-value will be approximate in the presence
## of ties

##
## Two-sample Kolmogorov-Smirnov test
##
## data: draw and a1
## D = 0.0847, p-value < 2.2e-16
## alternative hypothesis: two-sided

title("c=0.1", outer=TRUE)</pre>
```

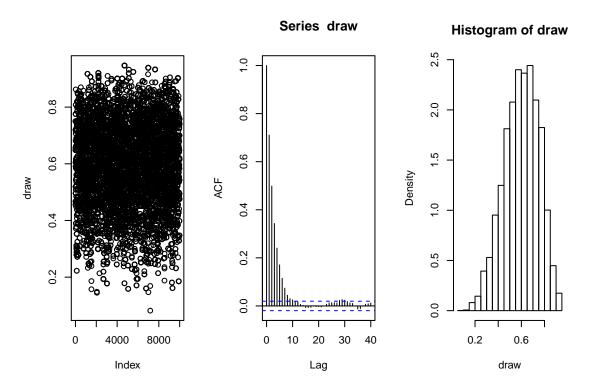

```
draw=MHalg(10000,2.5)
par(mfrow=c(1,3),oma=c(2,2,2,2))
plot(draw); acf(draw); hist(draw,freq=FALSE)
ks.test(draw,a1)

## Warning in ks.test(draw, a1): p-value will be approximate in the presence
## of ties

##
## Two-sample Kolmogorov-Smirnov test
##
## data: draw and a1
## D = 0.014, p-value = 0.281
## alternative hypothesis: two-sided

title("c=2.5", outer=TRUE)
```

c=2.5

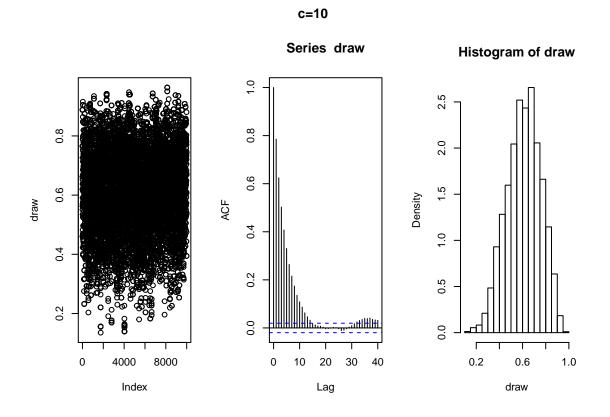

```
draw=MHalg(10000,10)
par(mfrow=c(1,3),oma=c(2,2,2,2))
plot(draw); acf(draw); hist(draw,freq=FALSE)
ks.test(draw,a1)

## Warning in ks.test(draw, a1): p-value will be approximate in the presence
## of ties

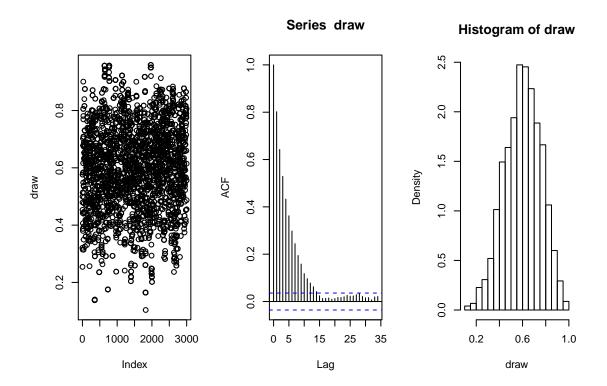

##
## Two-sample Kolmogorov-Smirnov test
##
## data: draw and a1
## D = 0.0338, p-value = 2.185e-05
## alternative hypothesis: two-sided
```

title("c=10", outer=TRUE)

Comparing histograms and Kolmogorov–Smirnov statistic, c=10 is the most effective. Now we lower the iteration to 3000. The result is already very close to beta(6,4)

```
draw=MHalg(3000,10)
par(mfrow=c(1,3),oma=c(2,2,2,2))
plot(draw); acf(draw); hist(draw,freq=FALSE)
```

```
a1=rbeta(3000,6,4)
ks.test(draw,a1)

## Warning in ks.test(draw, a1): p-value will be approximate in the presence
## of ties

##
## Two-sample Kolmogorov-Smirnov test
##
## data: draw and a1
## D = 0.0197, p-value = 0.6075
## alternative hypothesis: two-sided
```
